Role and Effectiveness of Amlodipine (Calcium Channel Blocker) in Expulsion of Ureteric Calculi

H K Garg¹, Ihsanullah Khan²

¹Professor, Department of Pharmacology, Gulf Medical University, Ajman, United Arab emirates.
²Professor & HOD Urology, Gulf Medical College (GMC), Ajman, United Arab Emirates.

ABSTRACT
Introduction: Urinary stones are being treated with calcium channel blockers (CCBs) such as Nifedipine. It loosens ureter muscles, thus facilitating expulsion of ureteric calculus. We decided to check whether Amlodipine, being safer and longer acting, can replace Nifedipine or not.

Materials and Methods: 120 patients above 18 years, both sexes, with confirmed ureteric calculi, were divided into a study group and control group. Amlodipine (CCB) and Loxoprofen (NSAID) were administered to study group, while the control group patients were kept on the non – steroidal anti-inflammatory (NSAID) only. The patients were followed up for 3 months for noting expulsion of ureter stone. Results were tabulated and analysed using SPSS 21 software, with Z test for proportion.

Results: Expulsion rate of ureteric calculi was significantly higher and achieved much earlier in the study group as compared to the control group (p<0.001). Females showed a better expulsion response as compared to males (p<0.05)

Conclusion: Among calcium channel blockers, Amlodipine is more effective, safer and longer – acting as compared to Nifedipine, which may cause serious ADRs, especially in cardiac patients and has been banned in many countries as well.

Key Words: Amlodipine, Expulsion, Ureteric stone.

INTRODUCTION
Urinary stones are quite commonly reported in Urology OPD and emergency. Various options are available for surgical treatment of stones that includes¹:

- Shock Wave Lithotripsy (ESWL)
- Ureteroscopy (URS)
- Percutaneous nephrolithotomy (PNL)
- Open Surgery

All the above surgical methods are painful, inconvenient, expensive and relented by the patient.

Rationale
Being non – invasive, Medical management is usually the preferable treatment option as compared to surgery. Calcium channel blockers are safer option in comparison to diuretics and steroids, which may cause many adverse effects such as electrolyte, sugar, uric acid, lipid profile disturbances². Reports are available in literature regarding effectiveness of calcium channel blockers, such as Nifedipine, but Nifedipine, being short acting, causes tachycardia and is dangerous in cardiac patients. Amlodipine being long acting, seems to be safer³ and this is to be verified in our patients.

No such study using Amlodipine has been taken up in at least UAE, for an important ailment like ureteric calculus.

OBJECTIVE
To verify the effectiveness of calcium channel blockers (Amlodipine) in expelling ureteric calculi in UAE patients. In most studies around the world, Nifedipine has been used to relax ureter. Hardly any research has been carried out with Amlodipine till now.

PATIENTS AND METHODS
Study settings
Department of Urology, GMC Hospital & Research Centre, Ajman, United Arab Emirates (UAE)

Study population
All Patients both male and female, visiting Department of Urology GMC Hospital and Research Centre –Ajman, UAE.

Research design
A cross sectional prospective study was carried out in patients of both sexes, with ureteric calculi reporting to urology OPD &
Emergency room of Gulf medical University, GMC hospital, Ajman, UAE. This was an open label research design in which the patients were in full knowledge of the medication being provided.

Inclusion Criteria
- All patients (males as well as females) above the age of 18 years presenting with a ureteric stone of size ranging from 0.5 cm to 1 cm.
- All such stones occupying the upper, middle, and lower segments of the ureter.

Exclusion Criteria
- Patients already having been operated for ureteric stone.
- Patients less than 18 years of age.
- Patients already on antihypertensive medications excluding Calcium channel blockers (CCBs).
- Patients intolerant to Amlodipine.
- Stone size larger than 1 cm.
- Patients with renal failure, serum creatinine > 3 mg/dl.
- Patients with risk factors for urosepsis, such as prolonged obstruction and associated infection.

Sample size
A total of 120 patients of both sexes (60 patients each, in the study as well as the control groups). The sample size has been calculated after taking into consideration the following facts:
- According to available clinical research reports, about 68% patients have spontaneous ureteric stone expulsion. However, 77% expulsion rate has been recorded with addition of Nifedipine.
- With a minimum sample size of 60 + 60 patients, the difference in these figures becomes statistically significant.
- Considering the power of the study as 80%, the sample size is appropriate.

Duration of study
6 months from the date of approval of the proposal from the ethical committee of GMC hospital and research center.

Study instrument & validation procedure
The study was carried out with the help of:
- Diagnosis by history and investigations
- Treatment with & without Amlodipine (a calcium channel blocker).

No questionnaire was used in this study. The investigation instruments such as CT scan & ultrasound etc. are already considered as validated. A clinical data information sheet was used to fill relevant clinical details of the patient.

Ethical issues
All patients were informed in detail about this study and their role; an informed consent was obtained. Gulf medical University Ethical Committee clearance was obtained prior to the study.

Methodology
Diagnosis was made based on history and radiological investigations, namely, ultrasound & spiral C-T Scan of the abdomen. Other urinary & hematological investigations such as routine urine examination, kidney function tests and blood sugar were also performed. Patients were randomly divided into two groups:
- Group A (study group on Loxoprofen (NSAID) + Amlodipine (calcium channel blocker))
- Group B (control group on NSAID Loxoprofen alone).

Group A patients were prescribed tablets of Amlodipine and Loxoprofen (NSAIDs).
Group B subjects were prescribed. Loxoprofen (NSAIDs) only. Tablet Rowatinex which contains olive oil was added to both groups to add bulk to the treatment prescription and patient satisfaction.

Doses of these drugs were as per requirement, literature, manufacturer directives and clinical judgment. Amlodipine dose ranged from 5 to 10 mg. Loxoprofen dose was between 180-360 mg (3-6 tablets per day), as per the formulation and requirement. Rowatinex dose varied between 1-2 tablet three times a day.

Patients were followed up in OPD for 3 months on fortnightly basis for stone expulsion, which was monitored by history, ultrasound examination, X rays and spiral CT during and at the end of the study. Imaging modalities like Ultrasound, X-ray and CT scan were used selectively according to situation and requirement to reduce cost of treatment.

Surgical intervention was advised in patients with recurrent attacks of colic, urinary tract infection and unchanging location of stone along with increasing hydronephrosis. New patients were included time and again, to compensate for patients who left study.

Feasibility of the proposed research
This study was quite convenient to carry out, because the patients were being treated by the investigators. The investigations were carried out in the same hospital (GMCH). Almost all of our patients had health insurance and these insurance companies bore all the expenses for diagnosis and treatment.

Data analysis & storage
The data were analyzed using SPSS 21 software, with the help of Z test for proportion. Simple percentage calculations were done in an excel sheet master chart.

Help of a senior statistician was taken for data analysis.

Time line
Patients of ureteric calculi suitable for study reporting at Urology OPD of GMC hospital, Ajman, were included in this study. About 6 months were spent in collecting and processing data from these patients and also for follow-up.

RESULTS
Equal number of males and female patients of ureteric calculus were included in the study in both, study as well as control groups.

Maximum number of patients belonged to 18 to 30 years age group, which is significantly higher number than in older patients (p<0.001). Minimum patients were in 50+ age group which is statistically significant (p<0.001). Incidence of ureteric calculus was not significantly different in both sexes (Table 1) in both the groups.

Average stone expulsion in females was achieved much earlier (≈ 80%; p<0.001) as compared to the males which is statistically significant.

The control group patients were not able to expel ureteric stones before 3 months. Only 5 to 6 percent patients experienced spontaneous stone expulsion. On the contrary, 85% patients of study group successfully passed out their ureteric stones, in less than 3 weeks. This contrast is highly significant (p<0.001)
DISCUSSION
Ureteric stones are reported usually at emergency room rather than in OPDs. Ureter cut to be relaxed and the stone needs to be flushed out by higher water intake. Since the stone size was less than 1cm in all patients, medical management was preferred, rather than surgical\(^7\).

Calcium channels are much safer as compared to diuretics\(^8\). Till now, Nifedipine has been used by urologists in most countries\(^10-13\). But, because of tachycardia caused by it, many cardiac patients died and it has been banned by many countries\(^4\). Amlodipine is a long acting dihydropyridine (DHP) class calcium channel blocker which relaxes smooth muscles, and is widely used as an antihypertensive drug\(^4\). We just thought of trying out Amlodipine and the results are highly optimistic. About 85% success was achieved with Amlodipine, within 3 weeks.

CONCLUSION
We are probably the first researchers to have used Amlodipine for expelling ureteric calculus. Being safer, Amlodipine should be preferred to Nifedipine in ureteric calculus patients.
